# Challenges in Astrodynamics

As a field, astrodynamics is incredibly demanding of scientific computing.

- Calculations are expensive, e.g. numerical integration, iterative solvers
- Data may be large, e.g. solar system ephemeris
- Equations are complicated, e.g. analytical Halo orbit approximations
- Unit errors are an easy trap!

## Good News

**Julia can help!** As others have found (including the talks shown below), Julia has enormous potential for scientific computing within the field of Astrodynamics!

# Let's plan a trip to Jupiter!

Introducing Astrodynamics research alongside GeneralAstrodynamics.jl!

## Goals

- Design a trajectory between Earth and Jupiter using simple models
- Highlight language features, and packages in the ecosystem, that meet the challenges of computational astrodynamics
- Present a new astrodynamics package, GeneralAstrodynamics.jl

## cadojo/ GeneralAstrodynamics.jl

Astrodynamics with units! Provides common astrodynamics calculations, plotting, and iterative Halo, Kepler, and Lambert solvers.

# Equations of Motion (R2BP)

How will our spacecraft move?

## Restricted Two-body Problem

Assume your spacecraft is only pulled by the gravity of **one** celestial body. Let  $\mathbf{r}$ ,  $\mathbf{v}$ ,  $\mu$  be the spacecraft's position, spacecraft's velocity, and celestial body's mass parameter respectively.

$$\begin{aligned}\dot{\mathbf{r}} &= \mathbf{v} \\ \dot{\mathbf{v}} &= -\mu \frac{\mathbf{r}}{||\mathbf{r}||}\end{aligned}$$

Write these dynamics into a function, and plug that function into a numerical integrator (i.e. the excellent `DifferentialEquations.jl`) **simulate** (a.k.a. **propagate**) your dynamics forward or backward in time.

### Tip

If your self-coded function allocates memory, your numerical integration **will** be sub-optimal. Use `ModelingToolkit.jl` and `AstrodynamicModels.jl` to generate fast functions for you!

A `'ModelingToolkit.ODESystem'` for the Restricted Two-body Problem.

The Restricted Two-body Problem is a simplified dynamical model describing one small body (spacecraft, etc.) and one celestial body. The gravity of the celestial body exhibits a force on the small body. This model is commonly used as a simplification to describe our solar system's planets orbiting our sun, or a spacecraft orbiting Earth.

# Hohmann Transfer

The first interplanetary transfer design they teach you!

Symbol	Label	Expression
$r_1$	Earth's orbital radius w.r.t. Sun	$1.496 \times 10^8$ km
$r_2$	Jupiter's orbital radius w.r.t. Sun	$7.786 \times 10^8$ km
$v_1$	Initial spacecraft velocity w.r.t. Sun	$\sqrt{\frac{2\mu}{r_1} - \frac{2\mu}{r_1+r_2}}$
$v_2$	Final spacecraft velocity w.r.t. Sun	$\sqrt{\frac{2\mu}{r_2} - \frac{2\mu}{r_1+r_2}}$

# Manifold Transfer Concept

Manifold-based interplanetary missions are a 3 step process.

1. Launch from Earth into a **stable manifold** within the Sun-Earth system
2. Perturb from the Sun-Earth Halo onto an **unstable manifold**
3. Transfer onto a **stable manifold** of the desired destination Halo orbit

Mission Phase: Phase One ▾

# Conclusions

*Julia and its package ecosystem let me be a (productive) lazy astrodynamics developer.*

## Language Features

- Julia's speed, unicode character support, and clever type system with multiple dispatch allow for fast, mathematically expressive, and easy-to-type astrodynamics code

## Ecosystem Packages

- `Unitful.jl` and associated extensions are fantastic unit-handling packages
- `DifferentialEquations.jl`, `ModelingToolkit.jl`, and model packages like `AstrodynamicModels.jl` let you type dynamics for **correctness**, not **computational efficiency**
- `Plots.jl` is very simple and intuitive to use

## Interested in Astrodynamics? Help out!

- I've had a lot of fun developing `GeneralAstrodynamics.jl`, and there's more work to do!
- Don't be shy about filing issues, making pull requests, and otherwise contacting me if you're interested in helping out with features. No astrodynamics experience is required!

Psst!

Hey everyone, switch your Twitter handles to your favorite Julia macros! I've claimed `@code_typed`.

Thanks, all!

- The Julia Programming Language, `Unitful.jl`, `UnitfulAstro.jl`, `DifferentialEquations.jl`, and `ModelingToolkit.jl` are **excellent** tools for scientific computing
- `Pluto.jl` is excellent for showing demos, concepts, and JuliaCon presentations 😊
- Thanks to Dr. Barbee for continued guidance relating to finding periodic orbits, and designing manifold-based interplanetary transfers
- Thanks to Dr. Mireles for providing well-explained and publicly available notes and periodic orbit-finding MATLAB code on his [website](#)

Finally, thank you for watching!

Slides are available at [jcarpinelli.dev/juliacon](http://jcarpinelli.dev/juliacon). Please don't hesitate to reach out with questions!

# Unicode, Units, Multiple Dispatch

Oh my!

## Unicode Characters Help with Equations

- Equations are mathematically expressive!

```
ṙ = -μ * (r / norm(r))
```

## Unit Handling with Unitful.jl

- Unitful.jl and extensions (i.e. UnitfulAstro.jl, UnitfulAngles.jl) are the best unit handling packages I've seen yet

```
using LinearAlgebra, Unitful
r = [0.0, 11_500, 0.0]u"km"
norm(r) == 11_500_000u"m"
```

## Multiple Dispatch and Speed

- Julia's type system allows for multiple equations for the same "calculation", e.g. orbital period calculations for different conic sections

```
period(a, μ) = 2π * √(a^3 / μ)
period(orbit::Orbit) = period(semimajor_axis(orbit), mass_parameter(orbit.system))
period(orbit::Orbit{Parabolic}) = Inf * timeunit(orbit.state)
period(orbit::Orbit{Hyperbolic}) = NaN * timeunit(orbit.state)
```

# Orbit Determination

Structures and functions for describing orbits!

## Scratchspace

### Circular Restricted Three-body Orbit

Synodic Cartesian State:

```
t = 0.0 s
r = [-0.124337 0.378513 1.104311] km
v = [0.092258 0.773022 -0.580882] km s^-1
```

### Circular Restricted Three-body System (Sun-Mars)

```
Length Unit: 2.279e8 km
Time Unit: 5.933903358476423e7 s
Mass Parameters: (1.327124400419393e11, 42828.37362069909) km^3 s^-2
```

```
@terminal let system = SunMars
.
.
.
orbit = Orbit(randn(3), randn(3), system)
print(orbit)
.
end
```
